Evaluating Reserves and Resources for Unconventional Plays

Herman G. Acuña

Ryder Scott Petroleum Consultants

CONSIDERATIONS FOR THE EVALUATION OF UNCONVENTIONAL RESOURCES

- Generally adjacent undrilled portions of the reservoir are considered as proved undeveloped locations...but...
- SPEE Monograph 3:
 - “Offset well performance is not a reliable predictor of undeveloped location performance.”
 - “Consequently, predicting the performance of any particular well prior to completion is virtually impossible.”
- **Implication:** reasonable certainty (P90) volumes for a single well or a small number of wells is generally **far below expectations for PUD**
 - Expect significant well variability even after the sweet spots have been identified

CONSIDERATIONS FOR THE EVALUATION OF UNCONVENTIONAL RESOURCES

- Apply probabilistic analysis to drilling portfolio – this entire program then becomes the minimum incremental project.
 - Continuous investment vs. front end loading
 - Continuous improvement and optimization
 - Learning curve
 - Relatively large resources volumes to production ratios

IMPLICATION OF THE RANDOM NATURE OF UNCONVENTIONAL RESOURCES

- Acreage position to diversify uncertainty can be very important.

Sigh! Thank you genius but if we knew that today neither of us would have a job, would we?

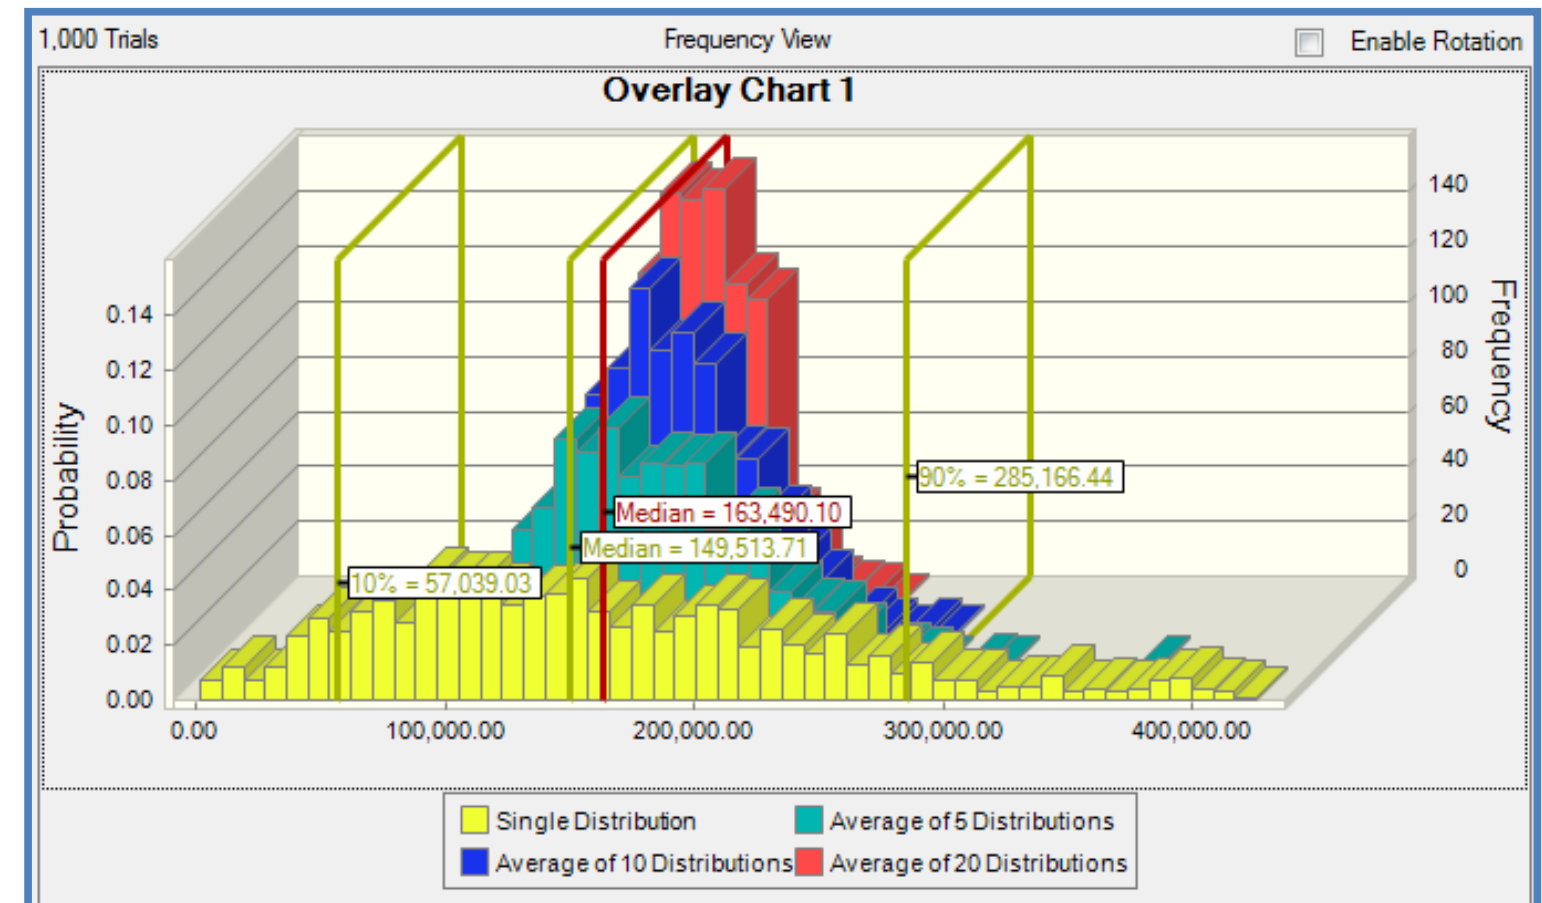

Same well may be assigned different reserves based on the company's acreage position!

That's not correct, the well is going to produce what the well is going to produce regardless of who the interest owner is!

PORTFOLIO EFFECT IN PROBABILISTIC AGGREGATIONS

- In statistical aggregation, except in the rare situation when all the reservoirs being aggregated are totally dependent, the **P90 (high degree of certainty) quantities from the aggregate are always greater than the arithmetic sum of the reservoir level P90 quantities**, and the **P10 (low degree of certainty) of the aggregate is always less than the arithmetic sum P10 quantities assessed at the reservoir level.**

PROJECT APPROVALS, FINAL INVESTMENT DECISIONS

- A company's staying power with a project that may initially not yield expected resources:
- Company A expects to heavily rely on the cash flow generated by the first few wells to pay back loans to drill these wells and finance the rest of the program - Very Risky, may never achieve portfolio expectations
- Company B has enough financial resources for the entire program and management fortitude to stay with the program – Likely to achieve portfolio expectations assuming properly estimated

- Gambler' s Ruin
- Company A enters a resource play with $\$n$ in cash and starts drilling where he wins with probability “ p ” and loses with probability “ $1-p$ ” The Company drills repeatedly, spending $\$$ (D&C) in each round. Company A leaves the play when total fortune reaches $\$N$ or it runs out of money (*ruined*), whichever happens first. What is the probability that Company A is ruined?

STAYING POWER AND GAMBLER'S RUIN

Bad Case Scenario: First Drilled wells are poor but do provide revenue to drill a few additional wells. Additional wells are usually worse than initial poor wells and development never exceeds 10 to 20 wells. Most IRRs very negative, a few positive. (No. of Cases: 14% - 4%)

Poor Scenario Case: First Drilled wells are not good, but provide enough cash flow to continue drilling. All IRRs are positive but less than 10%; consequently NPV10 are negative. (No. of Cases: 6% - 4%)

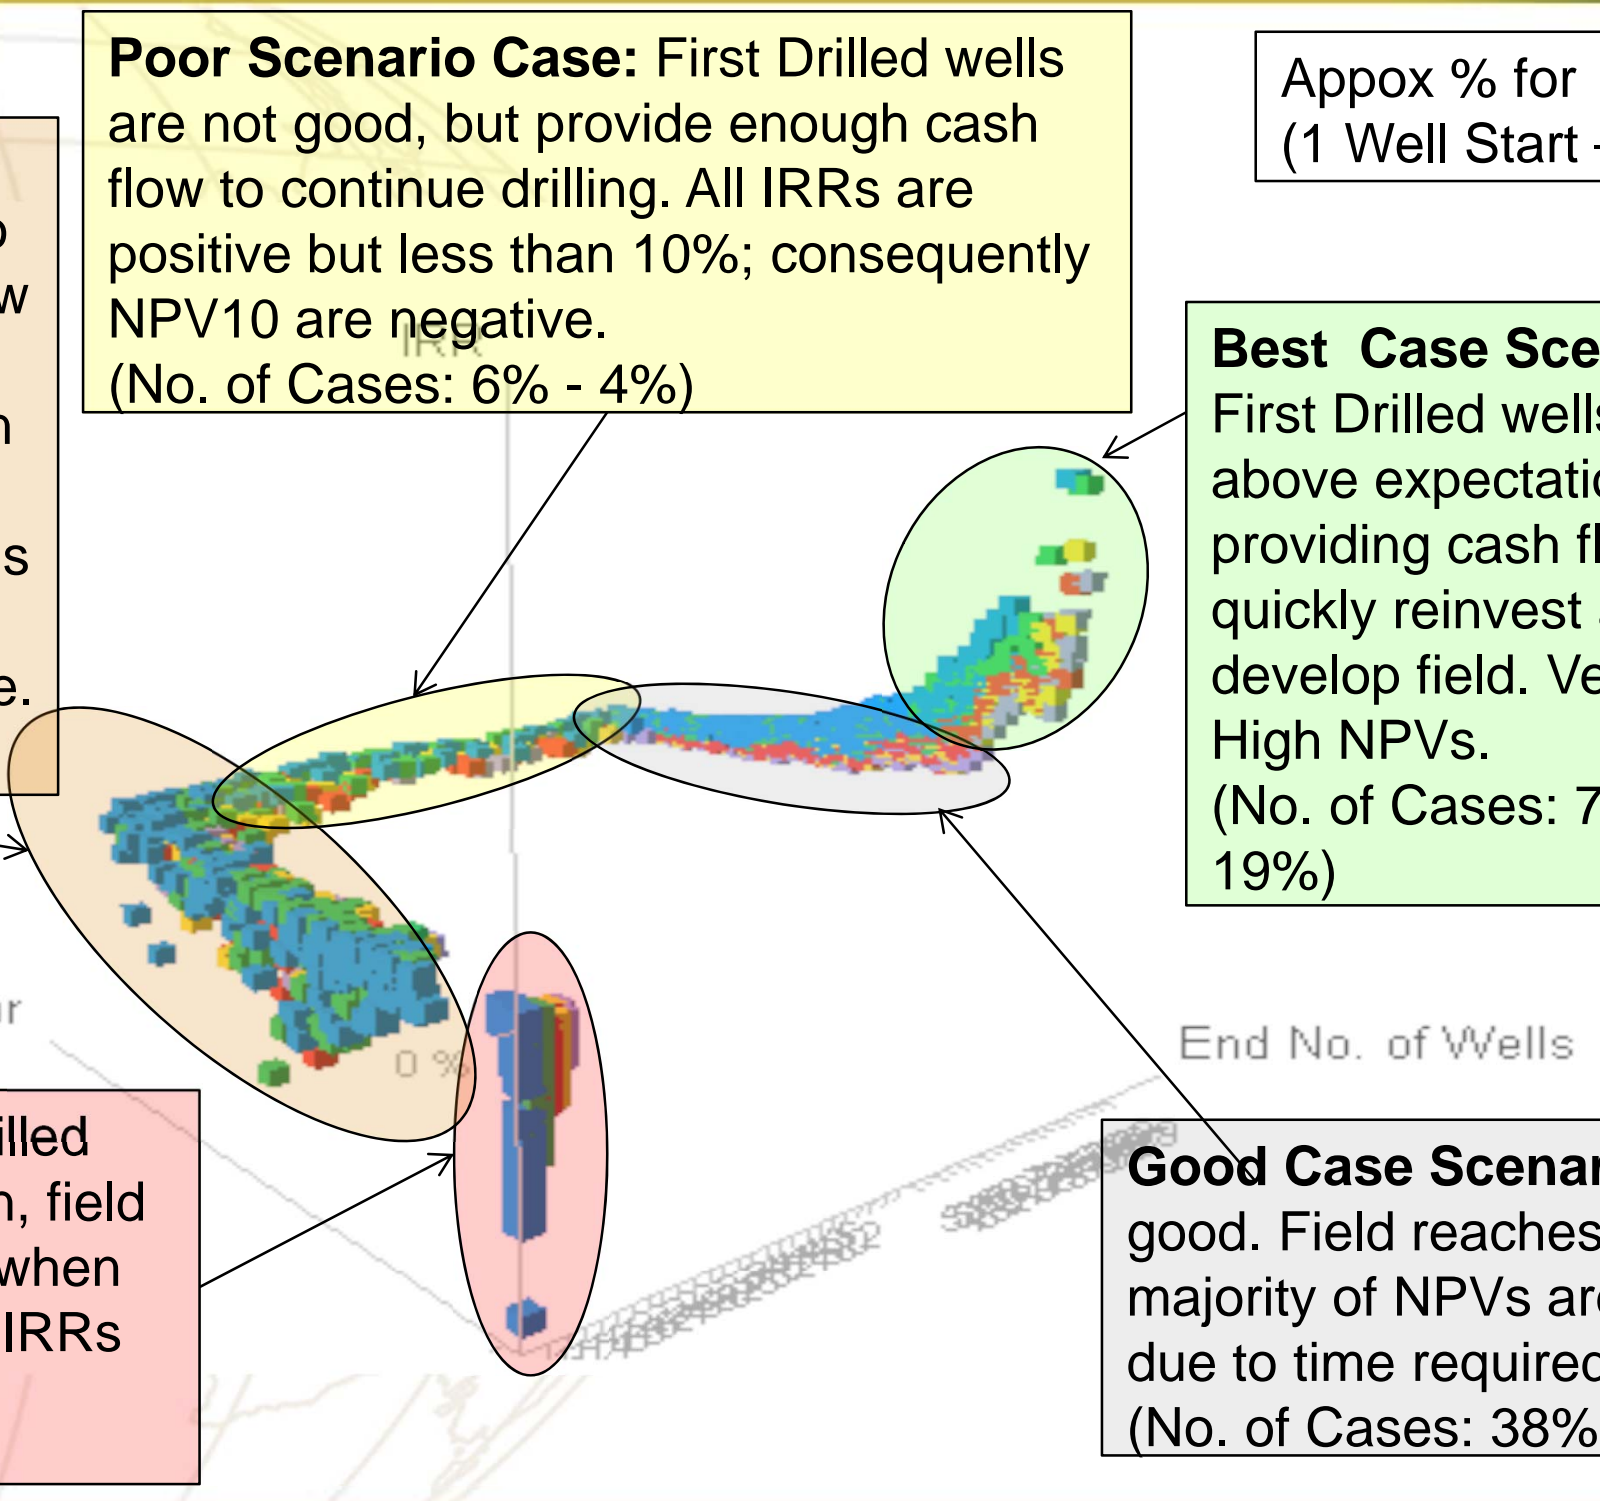

Approx % for
(1 Well Start – 5 Well Start)

Best Case Scenario: First Drilled wells are above expectations providing cash flow to quickly reinvest and develop field. Very High NPVs. (No. of Cases: 7% - 19%)

Data table:

● 3
● 4
● 5

Worst Case Scenario: First Drilled wells have such poor production, field developments cannot continue when relying on future cash flows. All IRRs extreme negative (No. of Cases: 35% - 6%)

Good Case Scenario: First Drilled wells are good. Field reaches full development. The strong majority of NPVs are positive, but low to moderate due to time required to develop the field. (No. of Cases: 38% - 67%)

1. Develop your well by well projections as you would normally do.
2. Confirm that there are no discernible trends or group the wells according to representative trends.
3. Develop the well level distribution(s).
4. Aggregate the distributions according to the program size and derive the distribution of type wells (average program distributions).
5. Select appropriate reserves for each reserves category according the percentiles (P90, P50, P10) in that distribution.

EVALUATION WORKFLOW – STEP 1

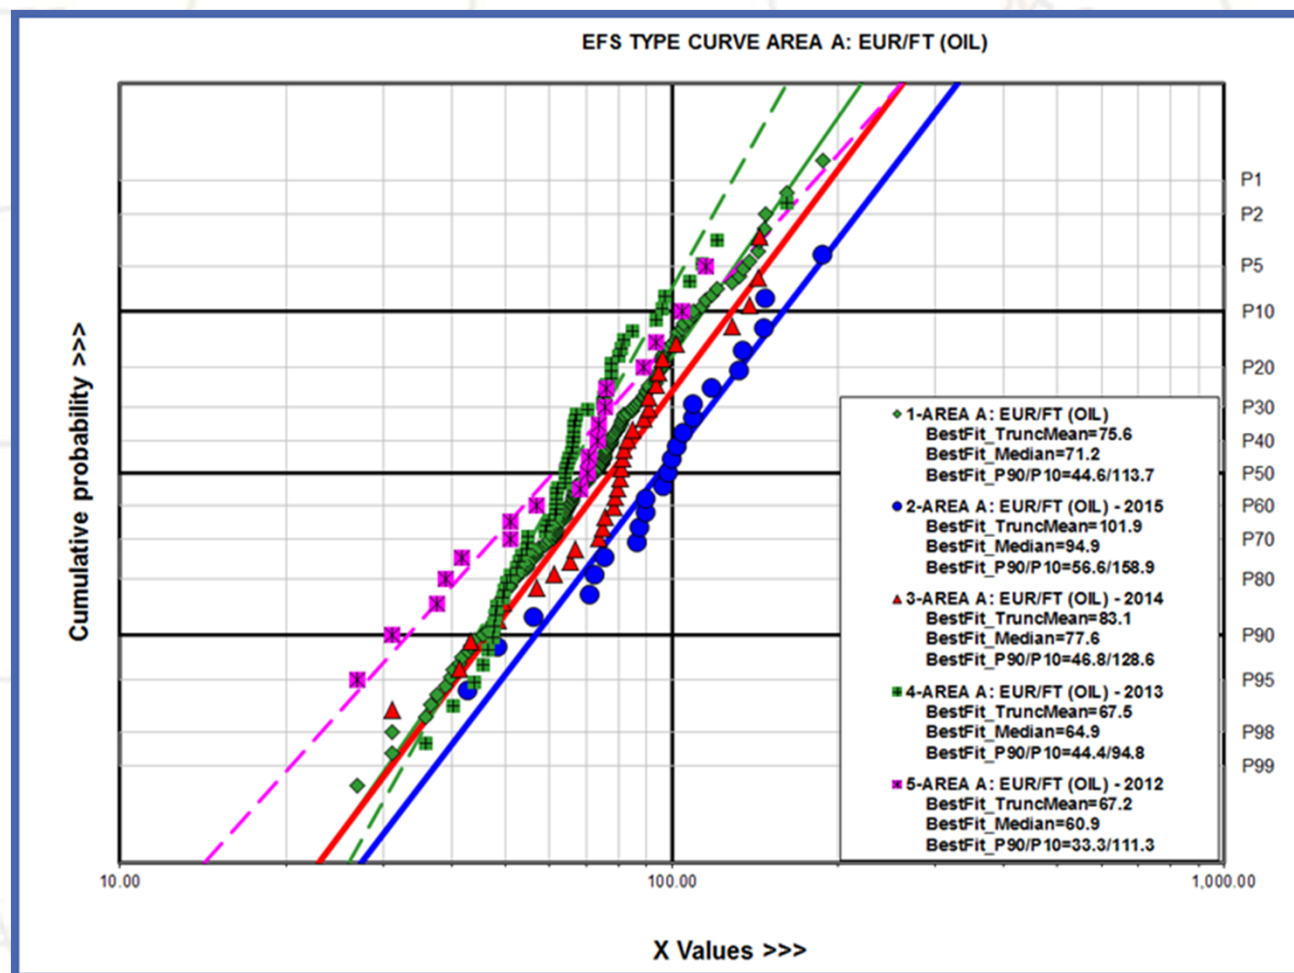

1. Develop your well by well projections as you would normally do.

- a) Initial rates
- b) b- factors
- c) Minimum declines
- d) Vintage effect?
- e) Multi-variable analysis

EVALUATION WORKFLOW – STEP 2

2. Confirm that there are no discernible trends or group the wells according to representative trends.

2. Develop well level distribution.

- After the SPEE Monograph 3 Spraberry Trend, Southwestern Martin County, Texas (pp. 45-46)
 - P90 = 31 kbbbls
 - P50 = 68 kbbbls
 - P10 = 144 kbbbls
 - Mean = 80 kbbbls
 - ρ^{\wedge} = 74 kbbbls
- These examples will be discussed in terms of EUR & EUR per well. Nevertheless, the concepts apply to any variable (bbls/ft, peak rate, etc.) used to determine reserves following the SPEE recommended probabilistic analysis.

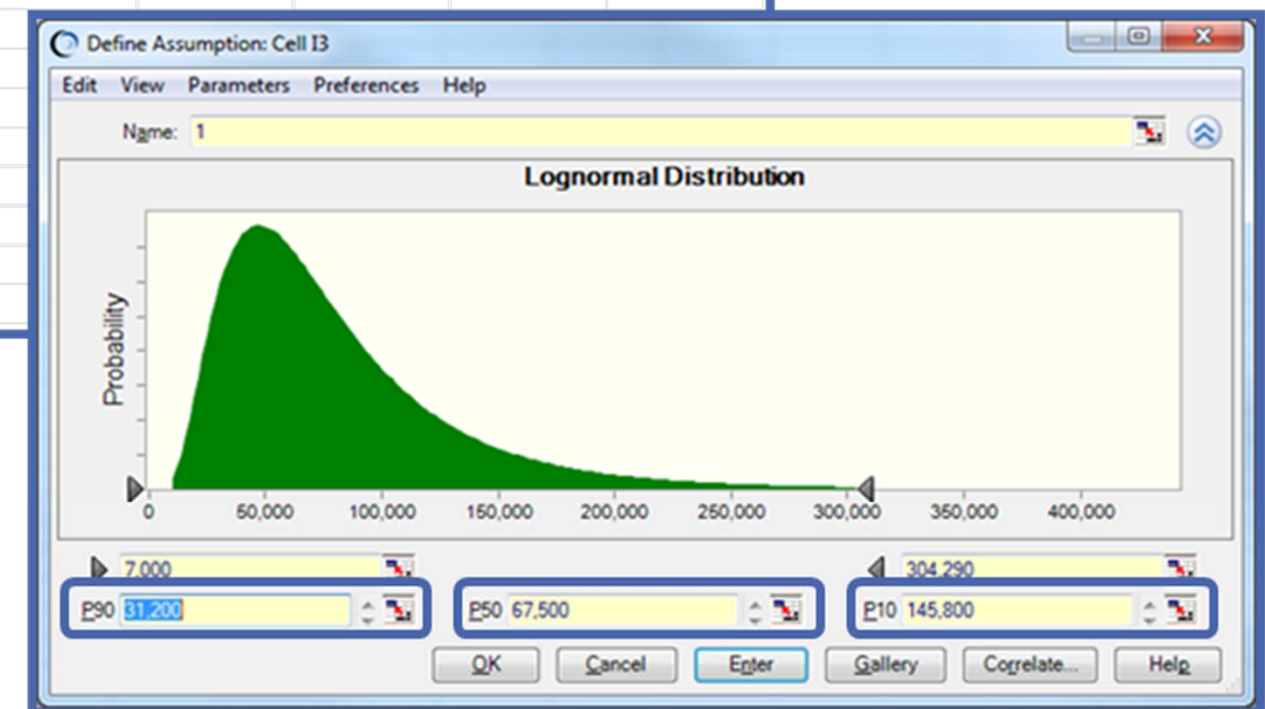

- Well level distribution
- Are these economic wells only or all wells?
- Should we be using a distribution of economic wells only and apply an economic COS factor?

EVALUATION WORKFLOW – STEP 4

4. Aggregate the distributions according to the program size and derive the distribution of type wells (average program distributions).

Well	Min	P90	P50	P10	Mean	Max.	Std. Dev	Dist	Forecast	Spraberry Trend	100 Loc.	8 Loc.	56 Loc.	28 Loc.

SAME WELL – DIFFERENT RESERVES

- “Wells exhibit a repeatable statistical distribution of estimated ultimate recoveries (EURs)”
- “A continuous hydrocarbon system exists that is regional in extent”
- **Problem: Acreage position may not be of regional extent and may vary from company to company**
- Implication: Same well(s) may be assigned different reserves based on the company’s acreage position.

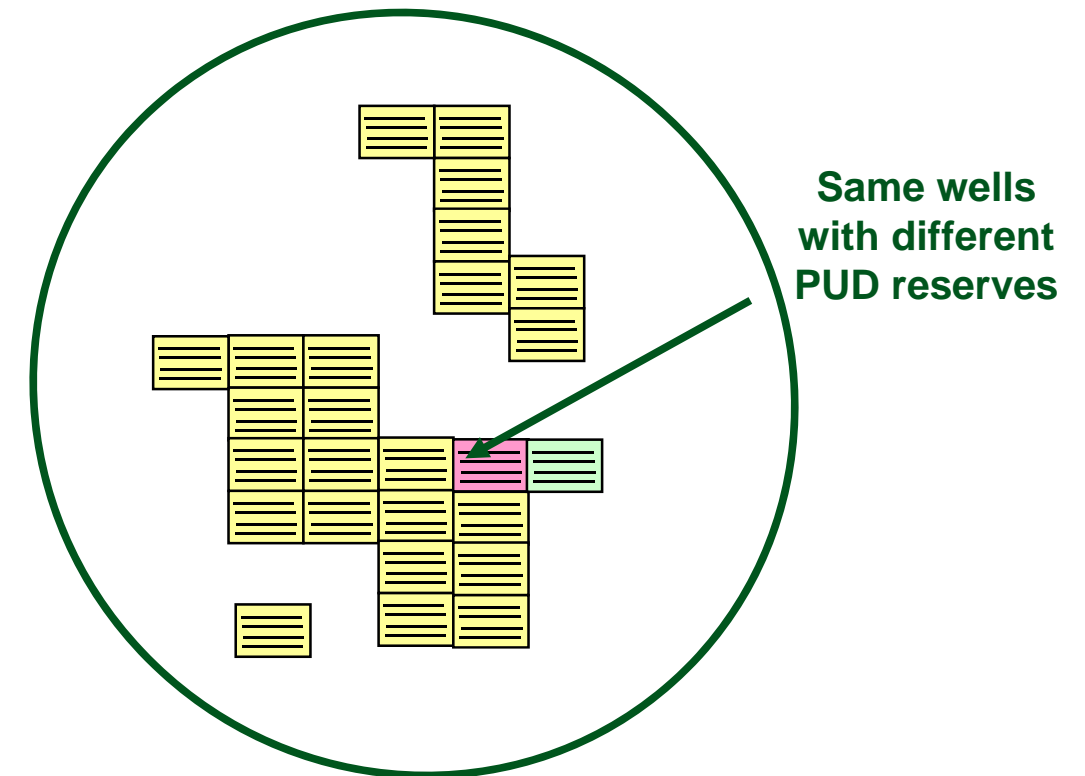

■ Company A acreage – 100 locations
■ Company B acreage – 8 locations
■ Company A & B acreage – 4 locations

SAME WELL – DIFFERENT RESERVES

	Per Well (kbbbls)		
	1P	2P	3P
Company A	73	79	85
Company B	59	78	102

- **Assign 1P reserves/well:**
 - 73 kbbbls for Company A (notice close to P[^])
 - 59 kbbbls for Company B
- **What about 3P – Higher for Company B?**

Company A acreage – 100 locations
 Company B acreage – 8 locations
 Company A & B acreage – 4 locations

A faint, light-colored globe with latitude and longitude lines is positioned on the left side of the slide.

THANK YOU
